

MIT International Center for Air Transportation

Distributed Simulation for Evaluating Low Noise ATC Procedures

Liling Ren and John-Paul Clarke

Massachusetts Institute of Technology

JUP Quarterly Review Meeting Summer 2003

Ohio University, Athens, OH

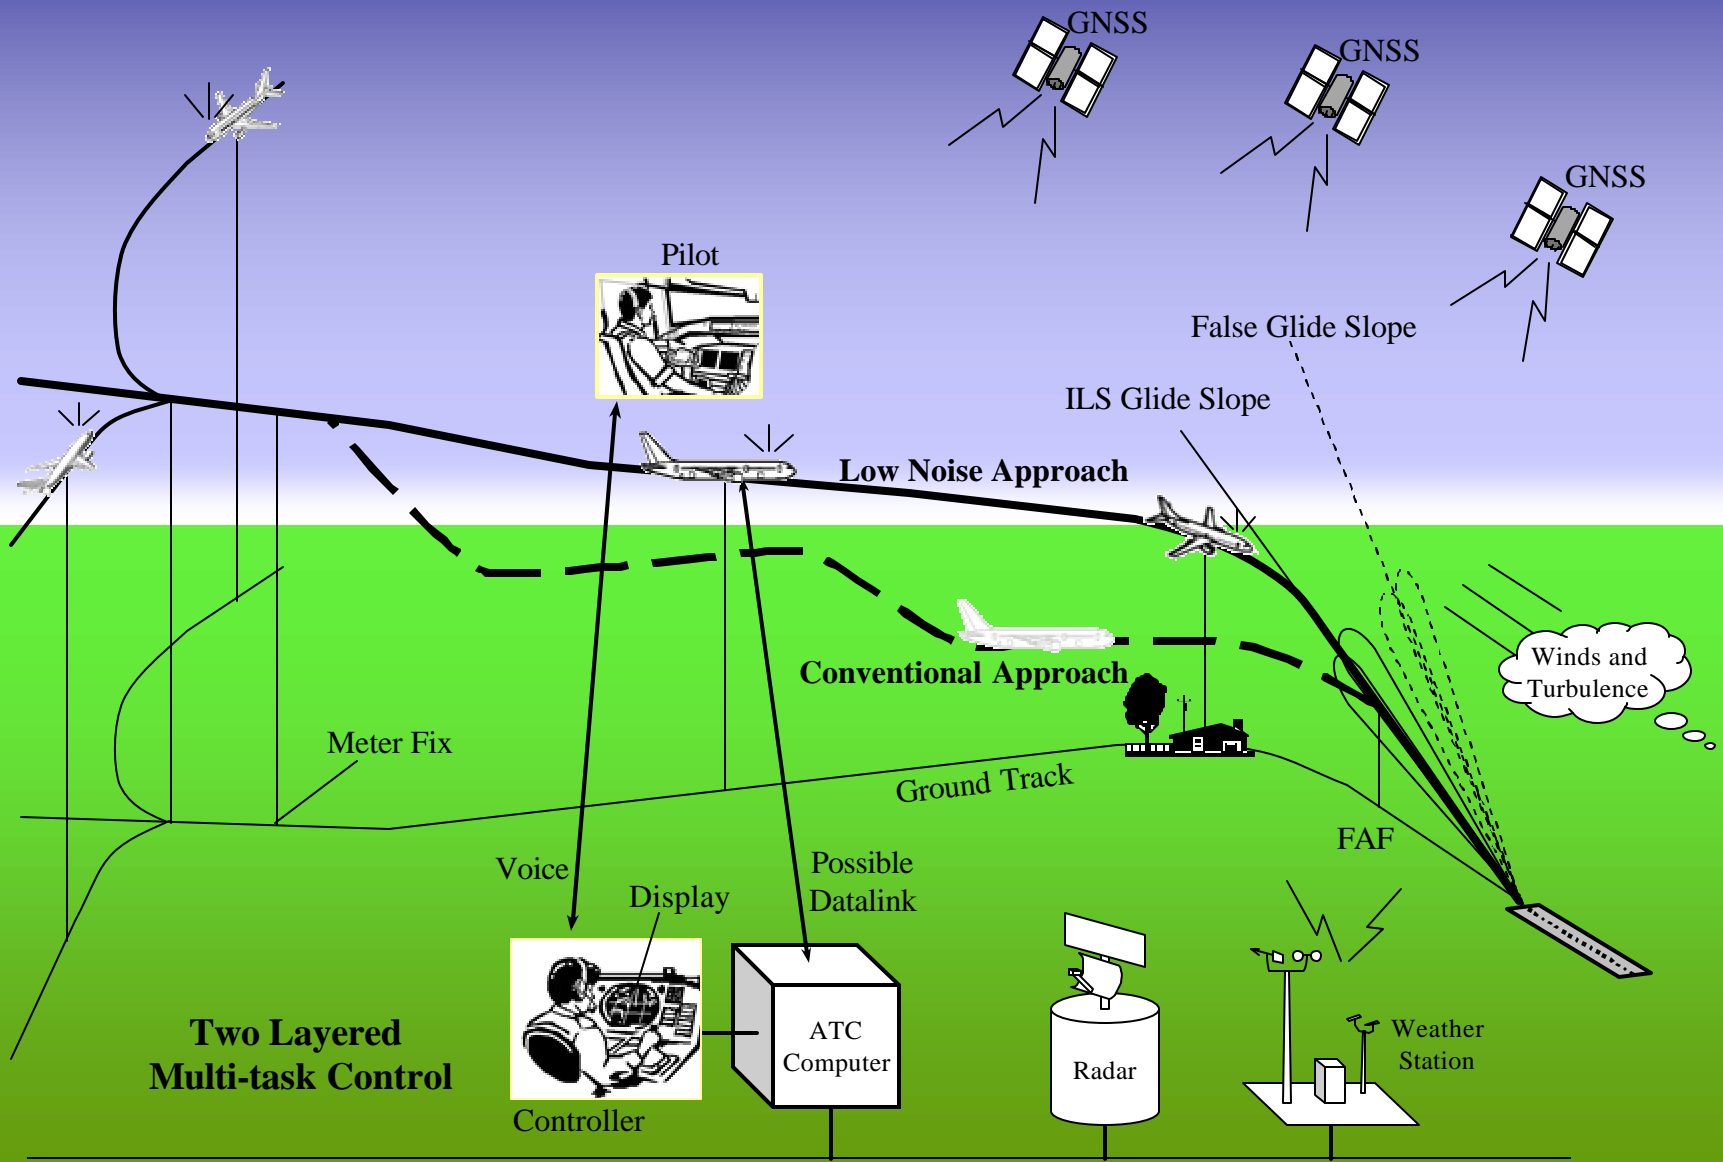

Louisville International Airport (KSDF)

KSDF is the home of UPS sorting hub, every night there are about 100 UPS jet aircraft arriving at the airport. Four miles north of the airport is down town Louisville. The simulation experiment will be based on approach to runway 17R.

Low Noise Approach and ATC Environment

Conventional ILS vs. Low Noise

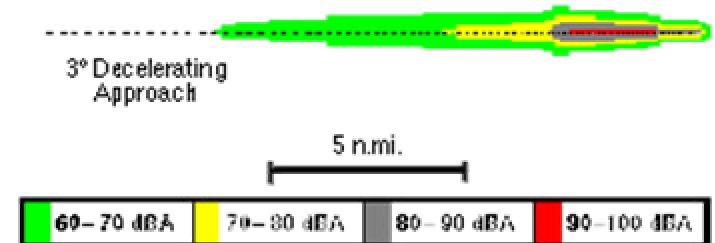

□ Conventional ILS Procedure

- Step-down descent
- Capture glide slope from below to avoid false slope
- Level flight at low altitude
 - Requires full power
- Higher noise

□ Low Noise Approach (LNA)

- Continuous descent
- Advanced technology enables capturing glide slope directly
- No level flight at low altitude
 - Use low power or idle
- Delayed flap extension
- Lower noise

Existing ATC Techniques

□ Primary Objectives of ATC

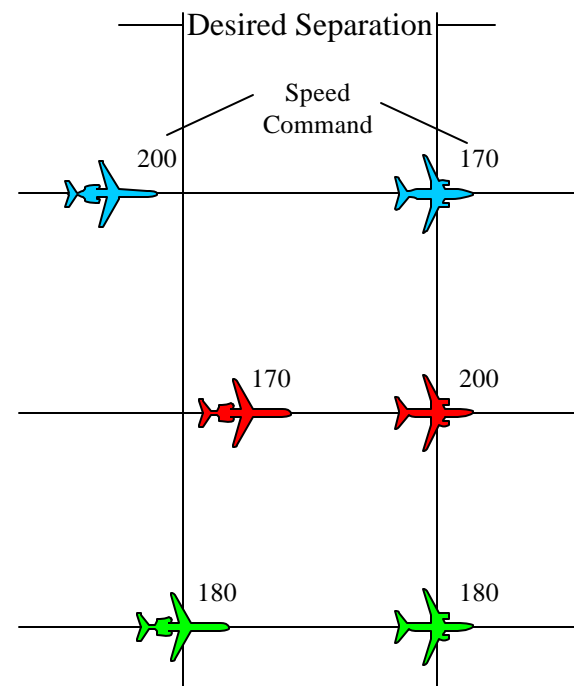

- Maintain safe separation between aircraft
- Organize and expedite the flow of traffic

□ Maintain Longitudinal Separation

- Use speed control to adjust separation
- Once desired separation is established, place aircraft at same speed
- No further speed intervention necessary after final approach fix (FAF) when aircraft capture glide slope

□ Results in

- Segmented constant speed approach

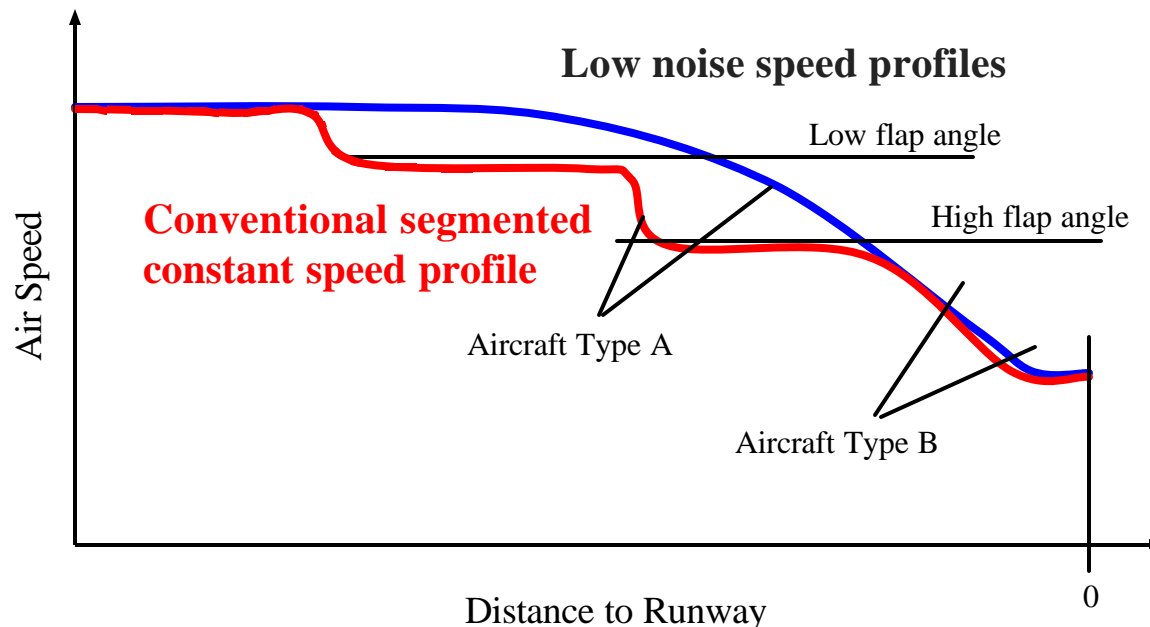

ATC Issues with Low Noise Approach

❑ Ideal Low Noise Approach

- Different aircraft follow different decelerating speed profiles
- Speed control can no longer be freely applied

❑ Controllers no longer able to manually separate aircraft without sacrificing capacity*

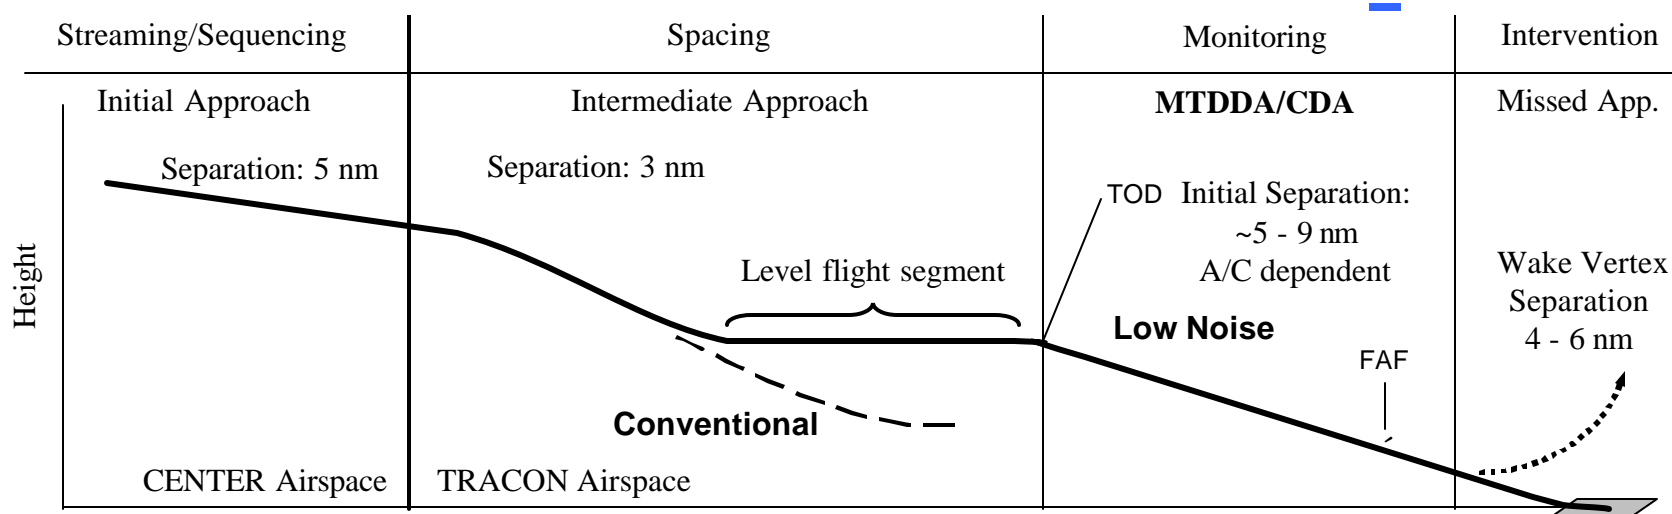

*Ho & Clarke, 2001

Procedure Design

□ Low Noise Approach with Intermediate Level Flight Segment

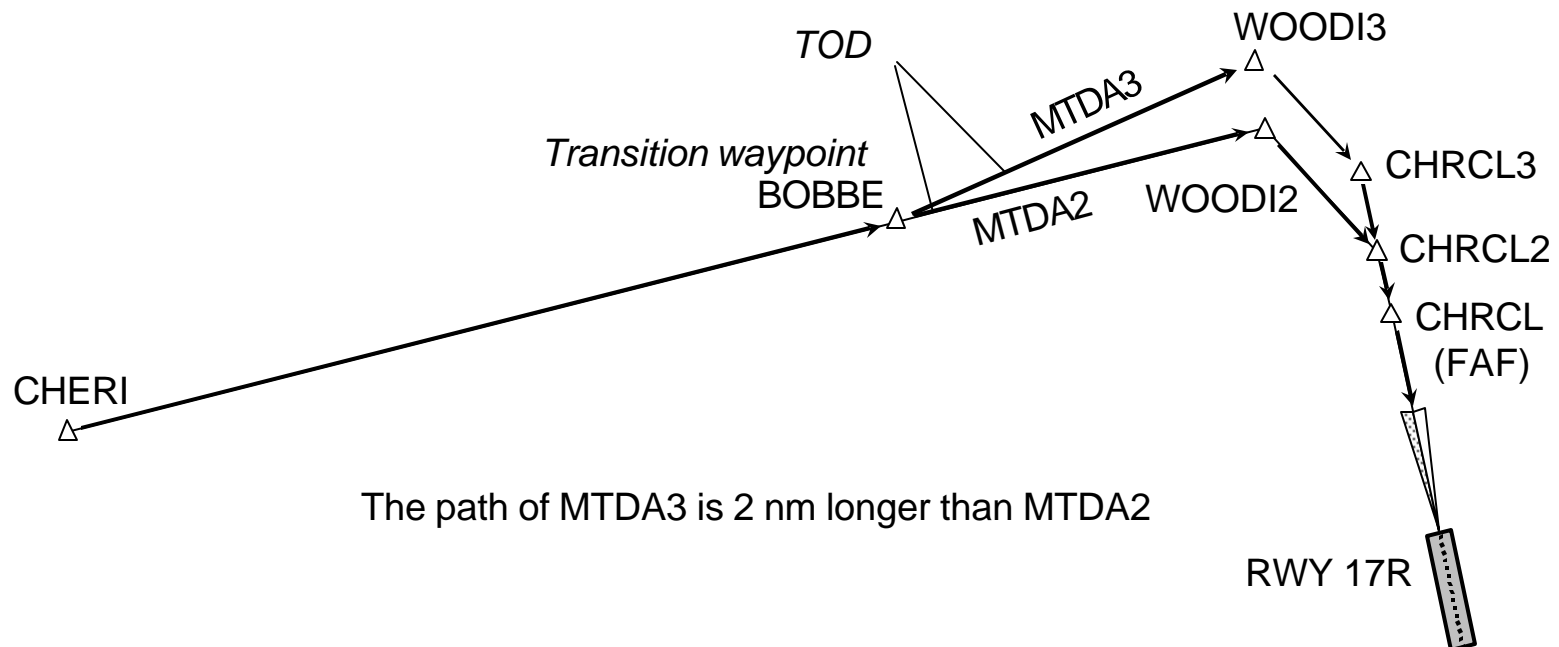

- Low noise descent starts from level flight at intermediate altitude
- Free to apply speed control before top-of-descent (TOD)
- Controller establishes initial separation and initial speed at TOD
- Preferably no controller intervention after TOD

Lateral Flight Path Stretching

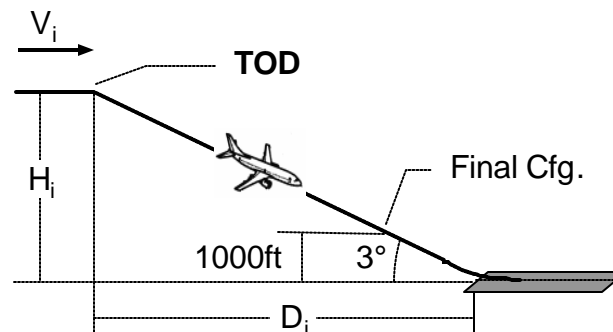

□ Provide Additional Separation Leverage after TOD

- Nominal lateral flight path is the shortest to save time and fuel
- Predefined stretched flight paths provide means to delay aircraft
- Stretched flight path selected by pilot via CDU upon receiving vectoring clearance from controller

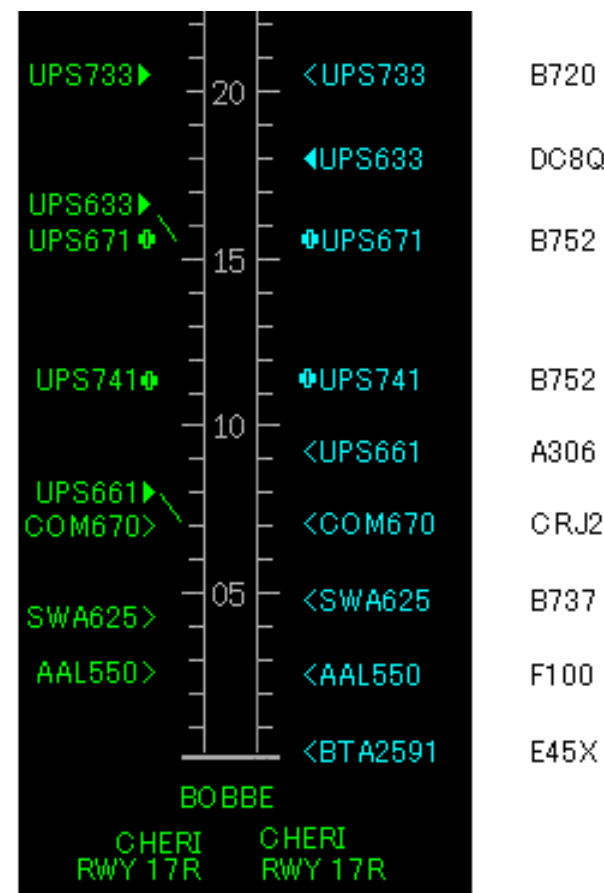

Low Noise Descent Segment

- ❑ **It Determines Initial Separation and Initial Speed at TOD**
 - Trajectory prediction, wake vortex spacing, and safety buffer
- ❑ **Ideal Profile Optimized for Noise Impact**
 - Different for different aircraft type, weight and wind estimates
 - Possible high variation due to operation uncertainty
- ❑ **More Structured, Robust and Stable Profile**
 - Use low power rather than idle
 - Restrict speed during the first half of the descent
 - To reduce complexity and improve conformance monitoring

□ Modify CTAS Time Line Tool for Spacing and Monitoring

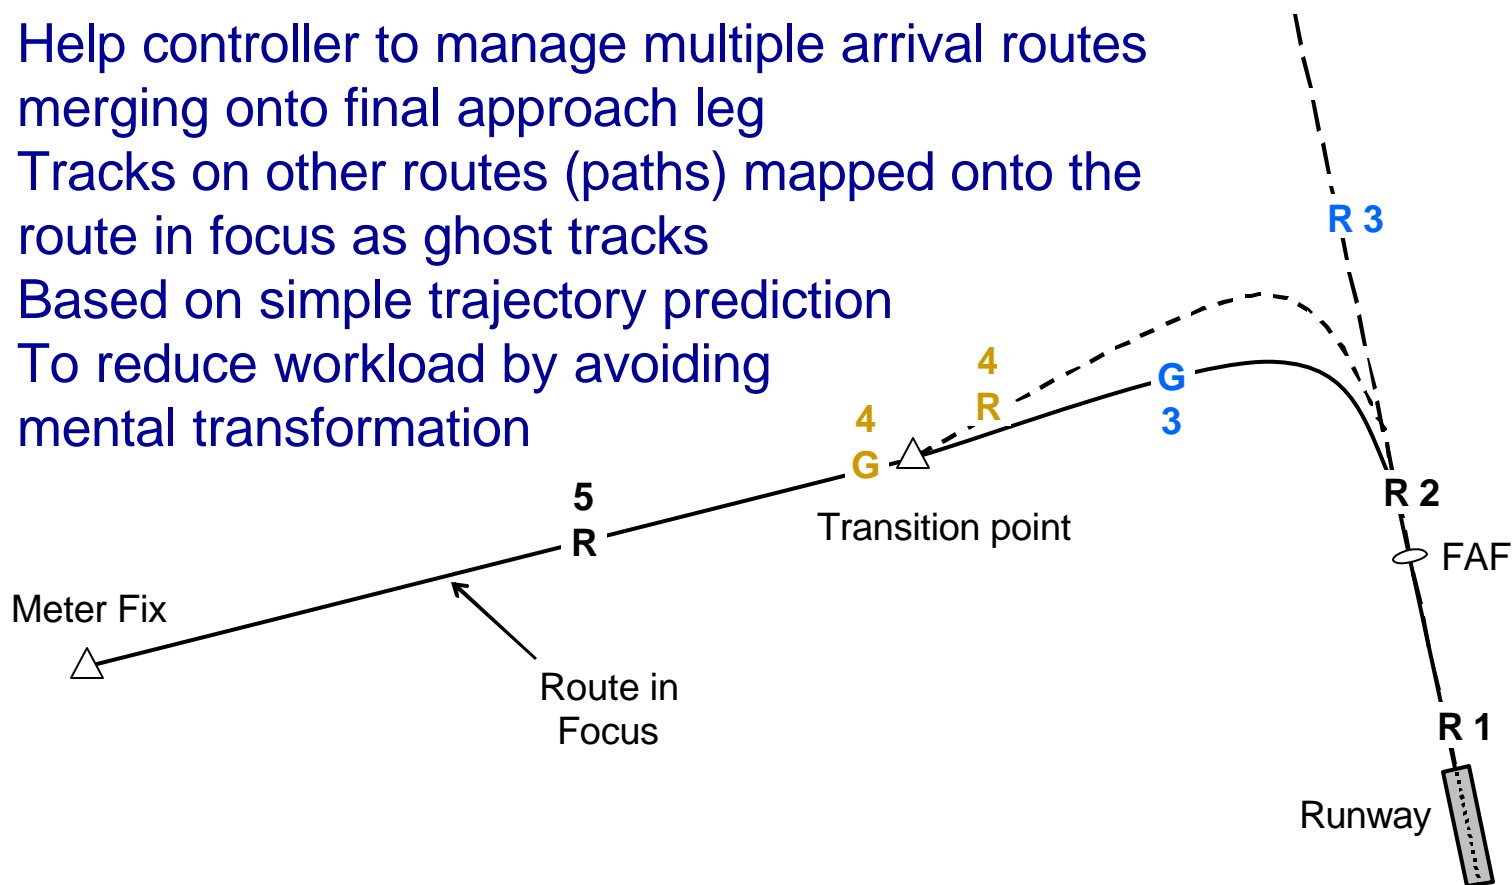

- Originally designed to improve controller situation awareness
- At the transition waypoint prior to TOD where path stretch occurs
 - Scheduled time of arrival based on aircraft type and winds to satisfy initial separation at TOD
 - Alert controller the necessity of lateral path stretch
- At runway threshold
 - Scheduled time of arrival based on wake vortex separation matrix
 - Alert controller for possible separation violation

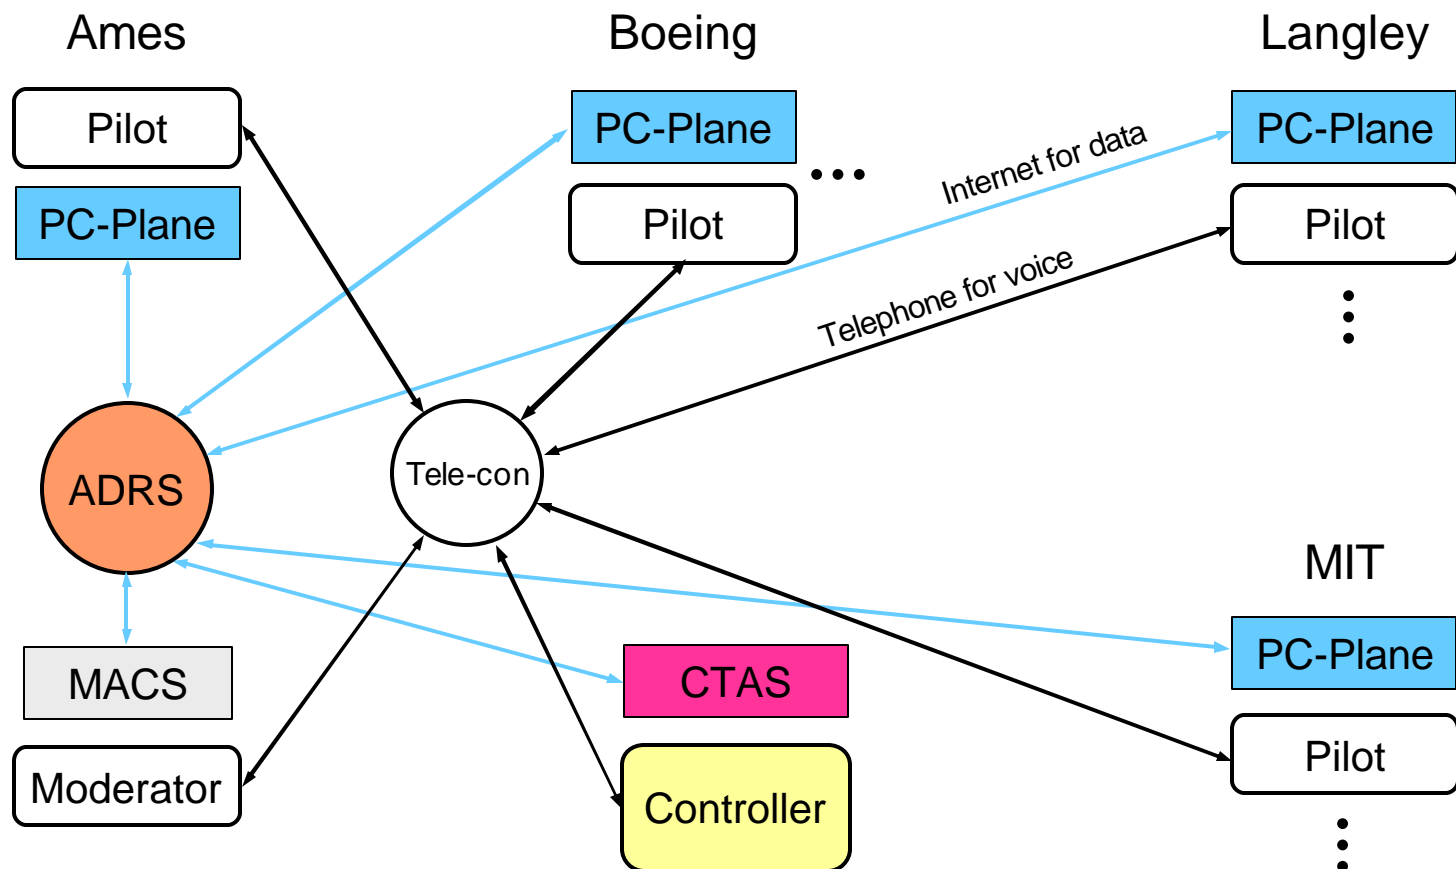

TMA Time Line Example
Modified from NASA Ames

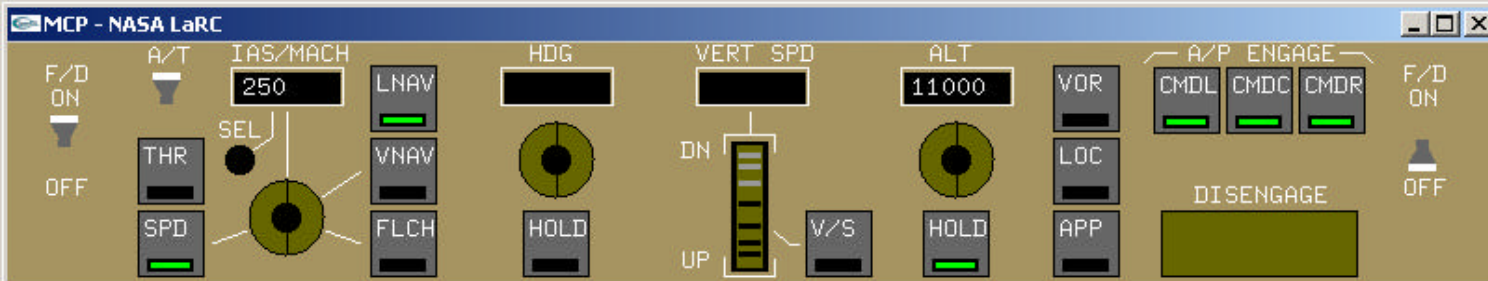

□ Develop a Ghost Display to Reduce Workload

- Help controller to manage multiple arrival routes merging onto final approach leg
- Tracks on other routes (paths) mapped onto the route in focus as ghost tracks
- Based on simple trajectory prediction
- To reduce workload by avoiding mental transformation

□ Hypotheses

- Air traffic control for low noise approach is more difficult for controller
- Automation tools – trajectory prediction, time-line, and ghost display – help to improve performance and reduce workload

□ Subjects

- Controllers
 - Professional controllers
 - Perform air traffic control tasks
 - Space aircraft for low noise approach
 - Merge aircraft onto final
- Pilots
 - Trained pilots or student pilots
 - Serve as agents to generate realistic traffic scenarios
 - Execute controller's commands

□ Independent Variables

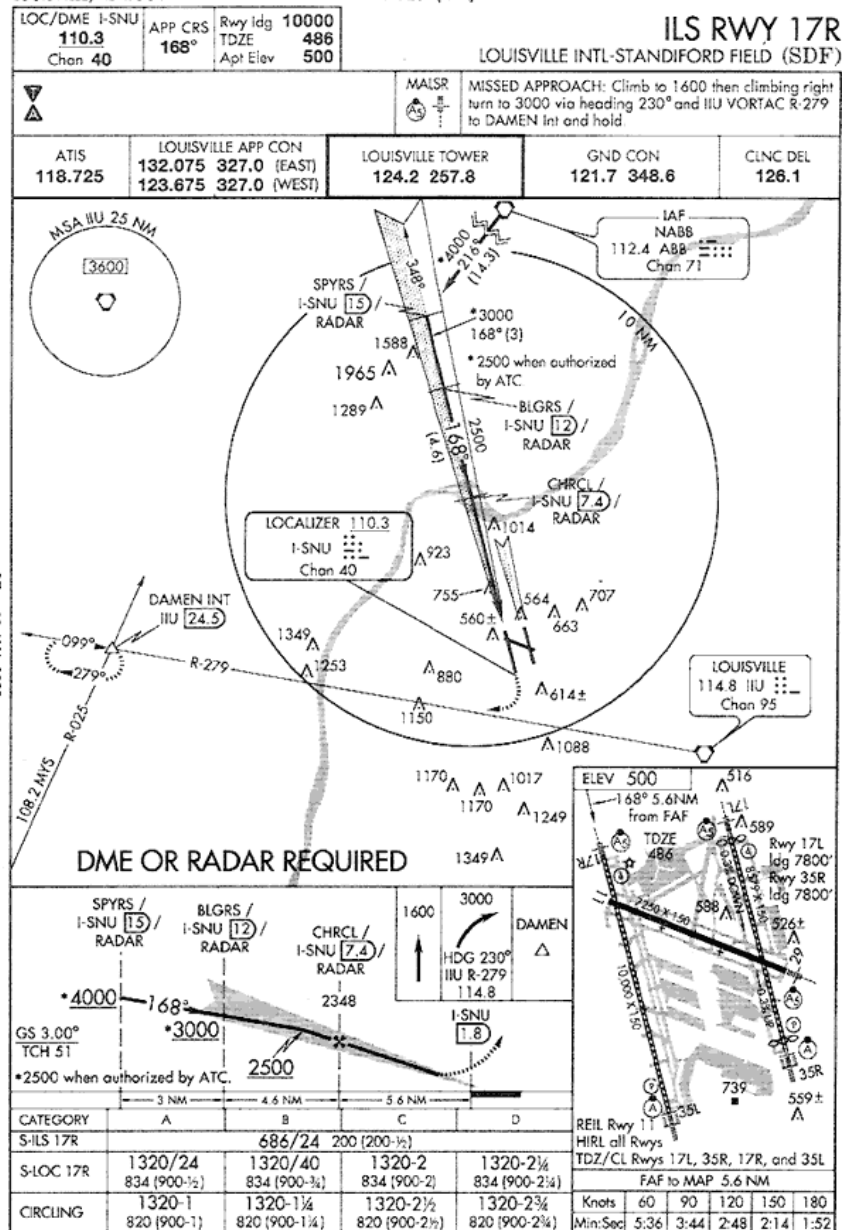

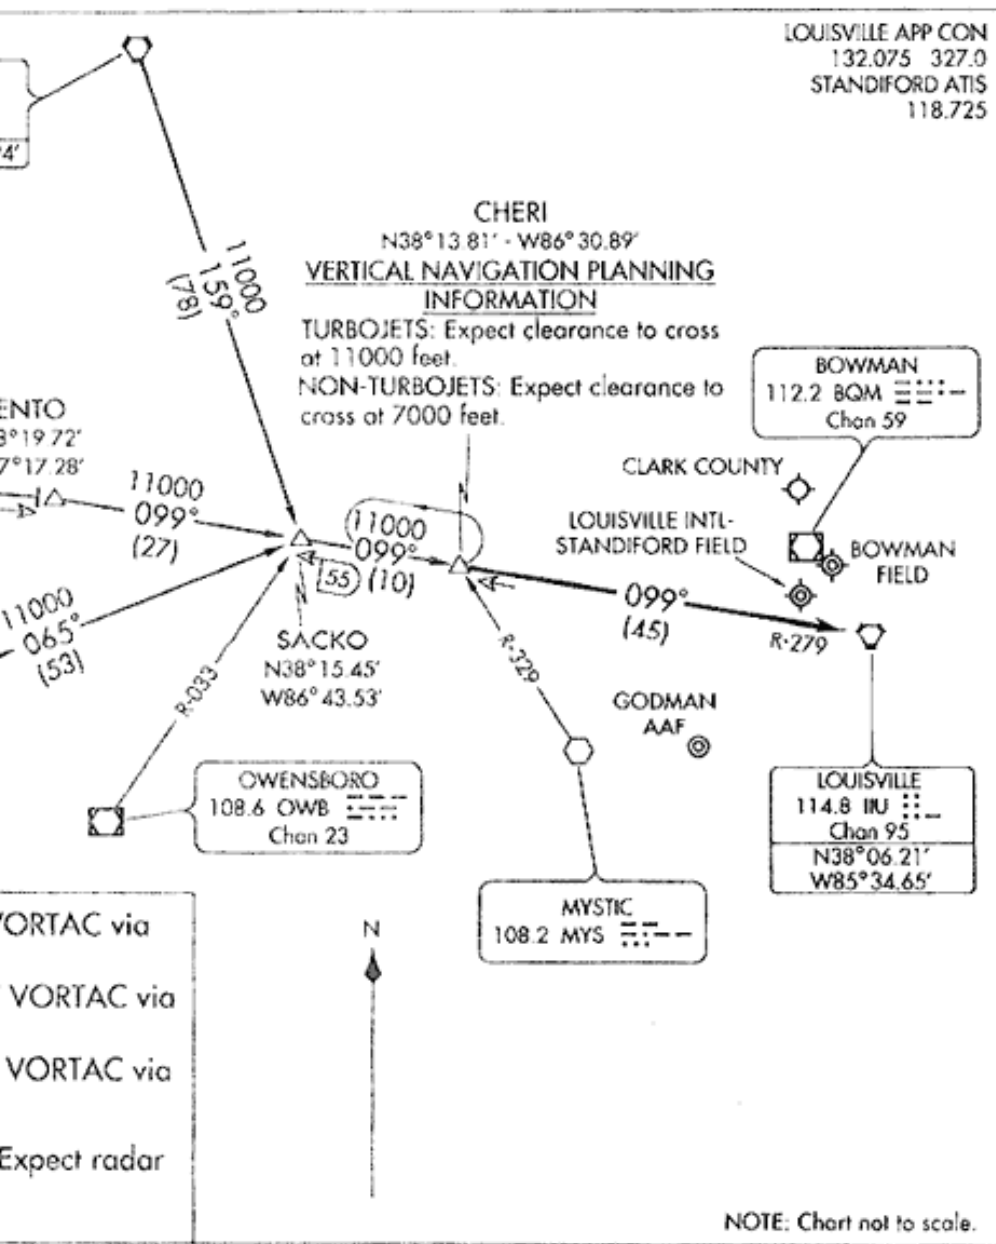

- Factors of Interest
 - Three (3) treatments of procedure and automation combinations
 - Conventional approach
 - Low noise without new tools
 - Low noise with new tools - time line and ghost display
 - Incoming traffic flow
 - Traffic flow rate (number of aircraft per hour), fixed for initial study
 - Variation of separation or time of arrival at meter fix, fixed for initial study
 - Aircraft mix, fixed for initial study, assume all FMS equipped
 - Winds uncertainty
 - Fixed for initial study
- Nuisance factors
 - Controllers vary in skills and experience, and personal preference
 - Pilots vary in skills and experience

□ Dependent Variables

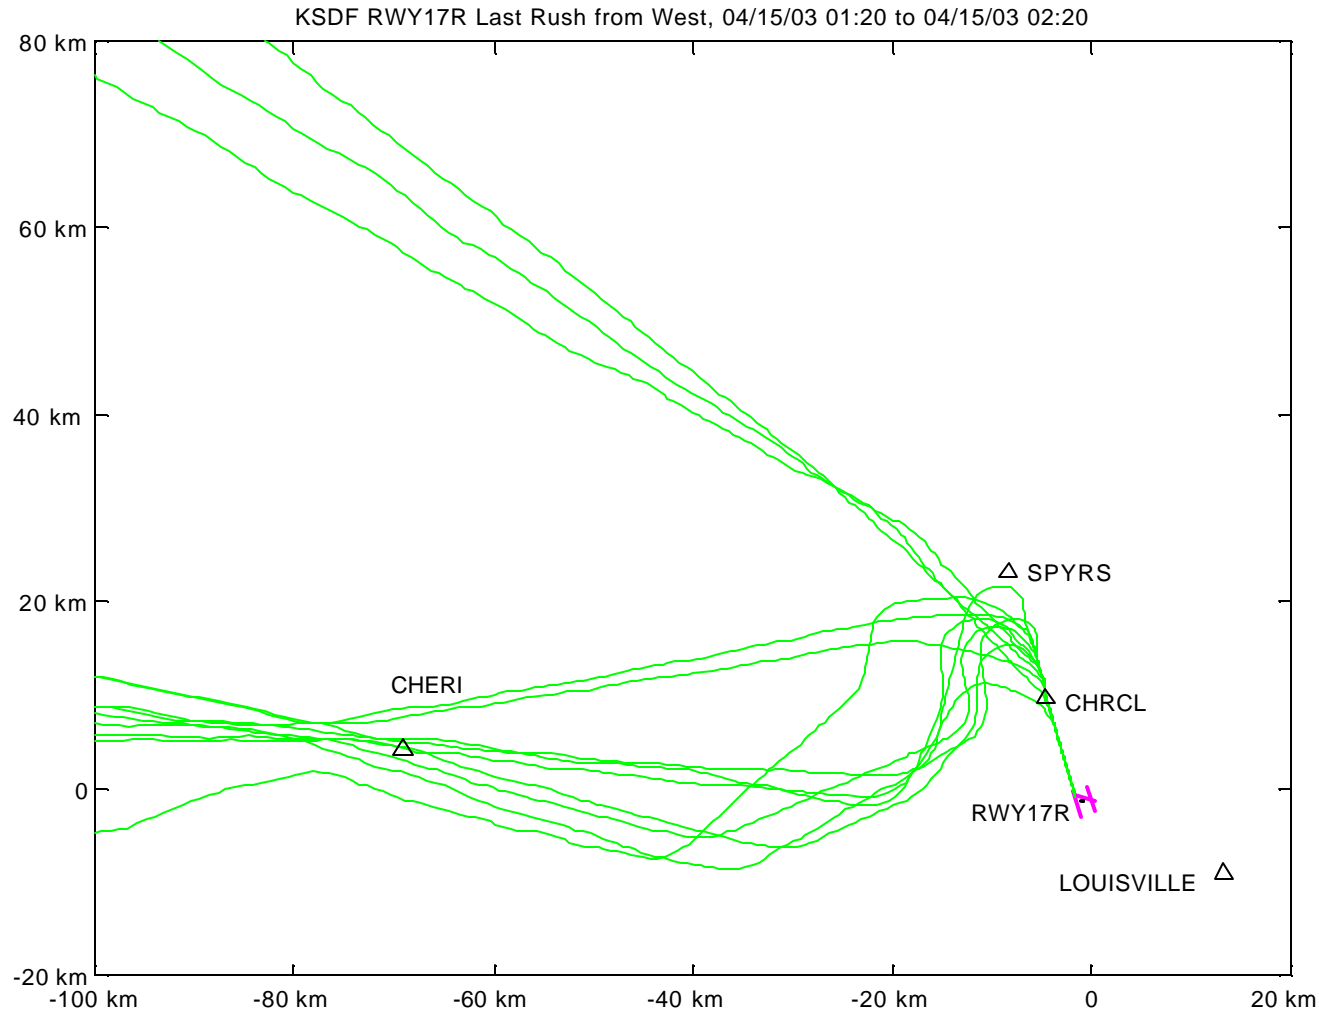

- Safety – number of separation violations
- Efficiency – actual flight time from meter fix to runway threshold
- Controller strategy – speed adjustment and flight path vectoring
- Workload – post test subjective Cooper-Harper type scale for each of the three treatment
- Situation Awareness – subjective Cooper-Harper type scale for each of the two automation tools
- Subjective preferences and acceptability - questionnaire

□ Test Plan

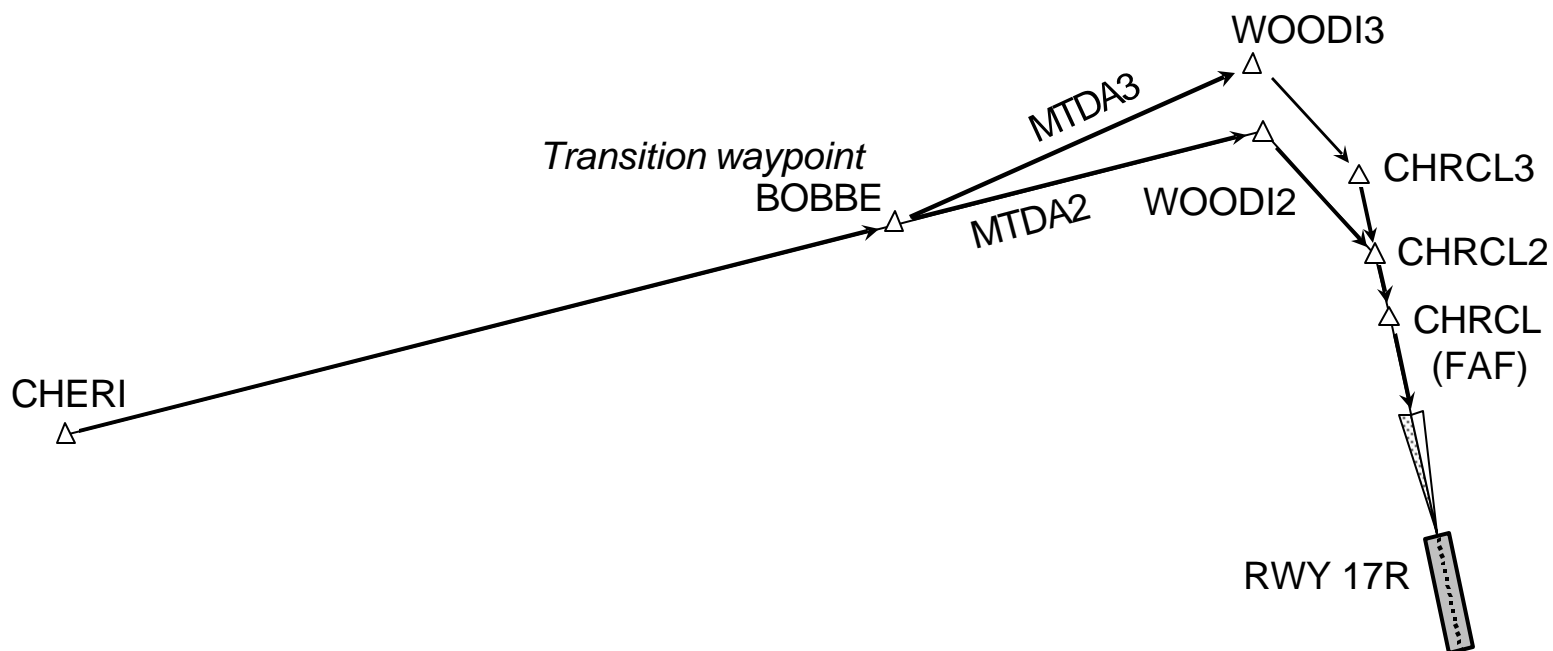

- Within subject treatment test design
- Use at least 6 controllers
- Randomly assign predefined order of treatments for each subject
- Randomly assign pilot to each airplane

Last Block of KSDF Night Arrival

Low Noise Arrival Chart

❑ Target Application

- UPS KSDF night arrival traffic flow landing to the south on runway 17R

❑ Traffic flow generation

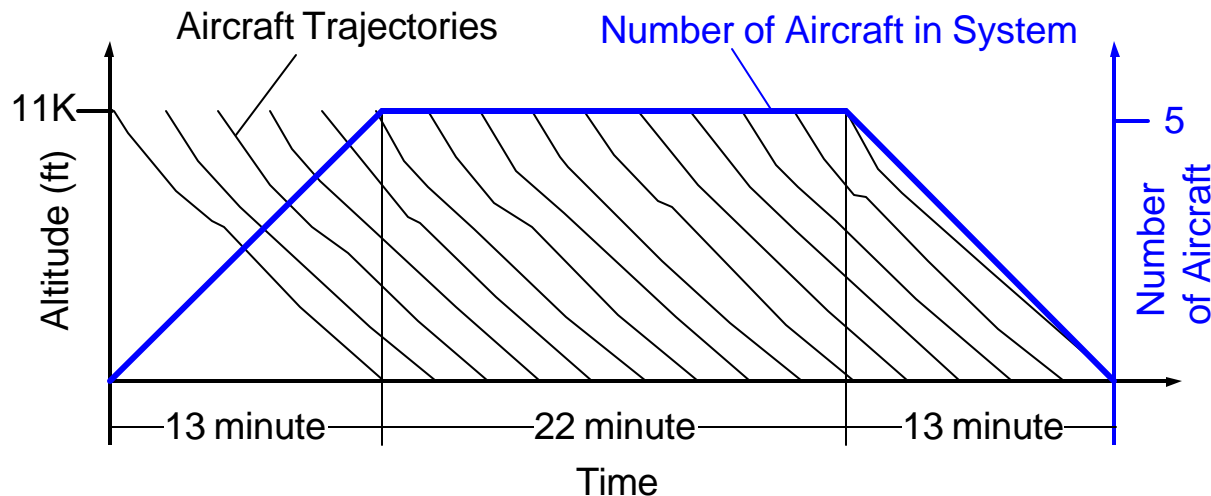

- Use recorded Passur flight track data (update rate 4.6 seconds)
- Modulated as incoming stream from west via CHERI
- With occasional straight in traffic from north via SPYRS
- Consists of only B767 and B757 aircraft
- Preserve traffic flow density (~33 aircraft per hour for two runways, 24 per hour for 17R, which is moderate)
- Preserve aircraft mix and time of arrival variation at meter fix

❑ Winds

- Annual average wind is used for initial study

□ Scenario Length

- Each scenario lasts about 50 minutes
- Assuming a traffic flow of 24 aircraft per runway per hour
 - Flight time is about 13 minutes from meter fix
 - Controller handles 15 aircraft in total
 - Controller works under peak flow for about 22 minutes

Experiment Protocol

❑ Trial Experiment

- Develop and fine tune procedures and clearance phraseology
- Train pilots to achieve consistent low noise profile
- Controller's task performed by researchers

❑ Controller Briefing and Training

- Briefing on low noise procedures
- Training runs performed with two aircraft
- Controller fully mast the control task and automation tools before formal experiment

❑ Formal Experiment and Data Analysis

- To start late 03 or early 04 if everything goes well
- Moderator coordinates pilots to generate traffic flow
- Actual time of arrival of each aircraft at meter fix generated randomly with variance depicting the real world traffic flow

☐ Explore Different Conditions

- Higher traffic
- Different levels of time of arrival variations at meter fix
- Include aircraft performing conventional approach
- Varying Wind conditions

☐ Explore Other Operation Concepts

- LNAV flight path interruption and recovery
- Operations with data link
 - Real time airborne trajectory computation with intent ADS-B downlink
 - Ground trajectory synthesis with procedure uplink
 - Are additional noise benefit worth the effort? Reducing system safety?

☐ We hope the distributed simulation would help probable flight test in the future
